AB - J57129842 Brilliant metal-like raised letter and figure exhibiting cubic effect are formed on the surface of a glass article e.g. glass bottle etc. simply by printing letter and/or figure on the surface of the glass article in heaped-up state with a printing ink. The ink is composed mainly of a synthetic resin exhibiting excellent affinity and stickiness to the glass, e.g. epoxy resin, foaming agent, e.g. NaHCO₃ and diazoaminobenzene, etc.

- The protruded printed part is heated to expand several times its volume by foaming, followed by adjusting the heating temp. to dry and make semi-hardened (practically non-sticky) protruded printed part, pressing on a hot stamping foil to form a brilliant metal-like print on the protruded printed part surface and finally heating the brilliant metal foil-printed protruded part e.g. at 130-200 deg.C so as to sinter.
